reported from the Colony of Aden since 1929. A few cases are treated almost every year in the Colony hospitals, but, with rare exceptions, they have occurred among immigrant families or among persons arriving from other ports. Vaccination against smallpox is compulsory for all residents of the Colony. In addition, intensive revaccination campaigns are undertaken by the health authorities whenever cases are discovered, or when outbreaks are reported from adjacent areas, as at the time of the epidemic in Mukalla in 1949. Although visitors to the Colony are required to possess valid certificates of vaccination, enforcement is sometimes difficult because of the large numbers of dhows and other small vessels which ply between Aden and Indian or African ports. Vaccination posts are established along the land frontiers on caravan routes from Yemen and Western Aden Protectorate, at which immigrants are examined, and, if necessary, vaccinated.

Other Infections. Pneumonia is widespread, ranking among the leading causes of death in both the Colony and the Protectorate. The fatality rate among the immigrant community in the Colony is unusually high, since many of the individuals who flock to the port in search of work or medical attention arrive in a debilitated condition. Sporadic cases of diphtheria are reported each year from the Colony. Chickenpox, measles, mumps and poliomyelitis are endemic. Localized outbreaks of meningococcus meningitis are recorded occasionally.

Diseases Spread or Contracted Chiefly Through Contact

Venereal Diseases. All forms of venereal diseases are observed among the civilian populations in Aden Colony. Syphilis and gonorrhea are reportable, but the statistics probably fail to give a true picture of the relative frequency of the different venereal infections. In 1948 and 1949, following the inauguration of a campaign for better re-
